I am trying to understand the difference between the segment tree and bucketization tree (which is used to store a set of integers from 1 to 8192). I found out that it has a complexity of $O(n \log n)$. To me, segment tree seems similar to bucketization tree. Is this true? Or am I missing something? Thanks! A: You're confusing segment tree with bucket tree. The latter is a data structure to store a set of ranges that can be partitioned into a collection of disjoint sub-ranges. The data structure has two properties: The size of the largest sub-range is bounded by $O(n)$. All ranges can be partitioned into a collection of disjoint sub-ranges in $O(n)$ time. A segment tree is a special case of a bucket tree with a trivial partitioning into one bucket. So in some sense the complexity of both the segment tree and bucket tree is $O(n)$. But, the bucket tree can have any range of size $O(n)$ and it can be partitioned in $O(n)$ time, whereas the segment tree can only partition one range. What's confusing here is the common understanding of these data structures. For a general range query, the bucket tree has the same $O(n \log n)$ query time complexity as the segment tree. But that's not the whole story. The range data structure has a number of additional optimizations in the literature. In particular, a "bucket tree" is a very specific data structure to minimize data movements and make other optimizations possible. Q: Creating a dynamic sql query So I'm trying to create a dynamic sql query which pulls out a list of orders and their status updates. I'm getting some errors when I try and combine the order id with the query, which is probably just a syntax error or something. I've been trying to work out the best way to do it and thought maybe I could use the code below, which basically tells sql to iterate through all rows in the orders table and create an update for each row. Any help would be greatly appreciated! declare @orders table (id int); declare @id int = 1 while @id
